

# **Organization of /sC-/ and /Cs-/ Onsets in Romanian**

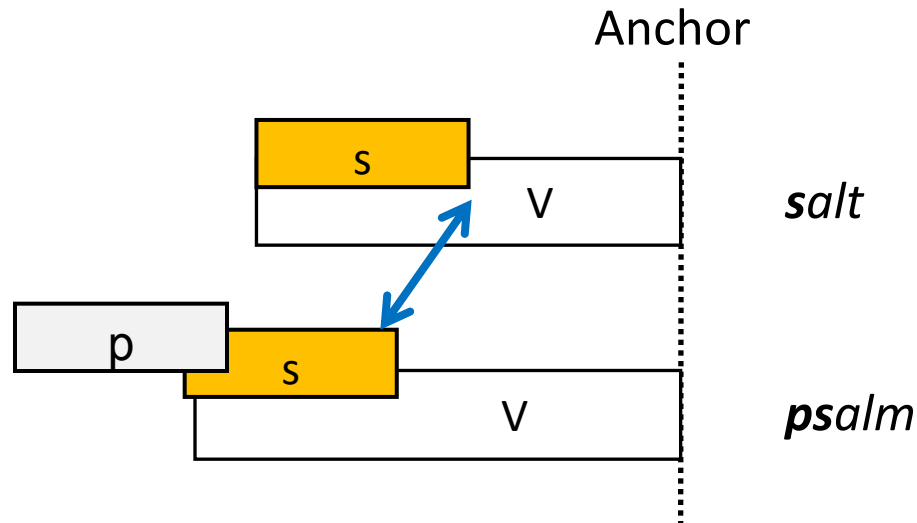

Stefania Marin

# Background

- Order of consonants in cluster plays a role in the temporal organization of onsets in relation to the following vowel
- Romanian sC onsets (SP-, SK-, SM-) C-center organized

- Romanian Cs onsets (PS-, KS-)

Prevocalic consonant shifted away from the vowel in stop-series

→ vowel lengthening

→ slowing down in production of the cluster words compared to the singleton words

# Current Study

- Are there order effects affecting the temporal relation of the two consonants in sC vs. Cs onset clusters?

Chitoran et al. 2002: front-to-back /bg-/ more overlapped than back-to-front /gb-;/ labio-coronal/coronal-labial less overlapped than other place combinations

Bombien, 2011: /kl-/ more overlapped than /kn-/

- If so, are such effects due (in part) to requirements on perceptual recoverability?

# Production Experiment: Materials and Method

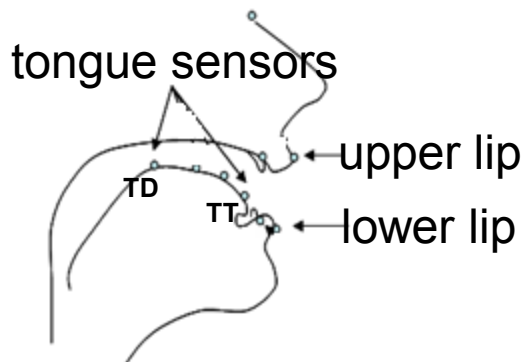

Stimuli (produced by 5 native Romanians):

**sC:** SP-, SK- (/ˈspalə/, /ˈskalə/)

**Cs:** PS-, KS- (/ˈpsalm/, /ksenoˈfob/)

## EMA Recordings

(AG500, Carstens Medizinelektronik)

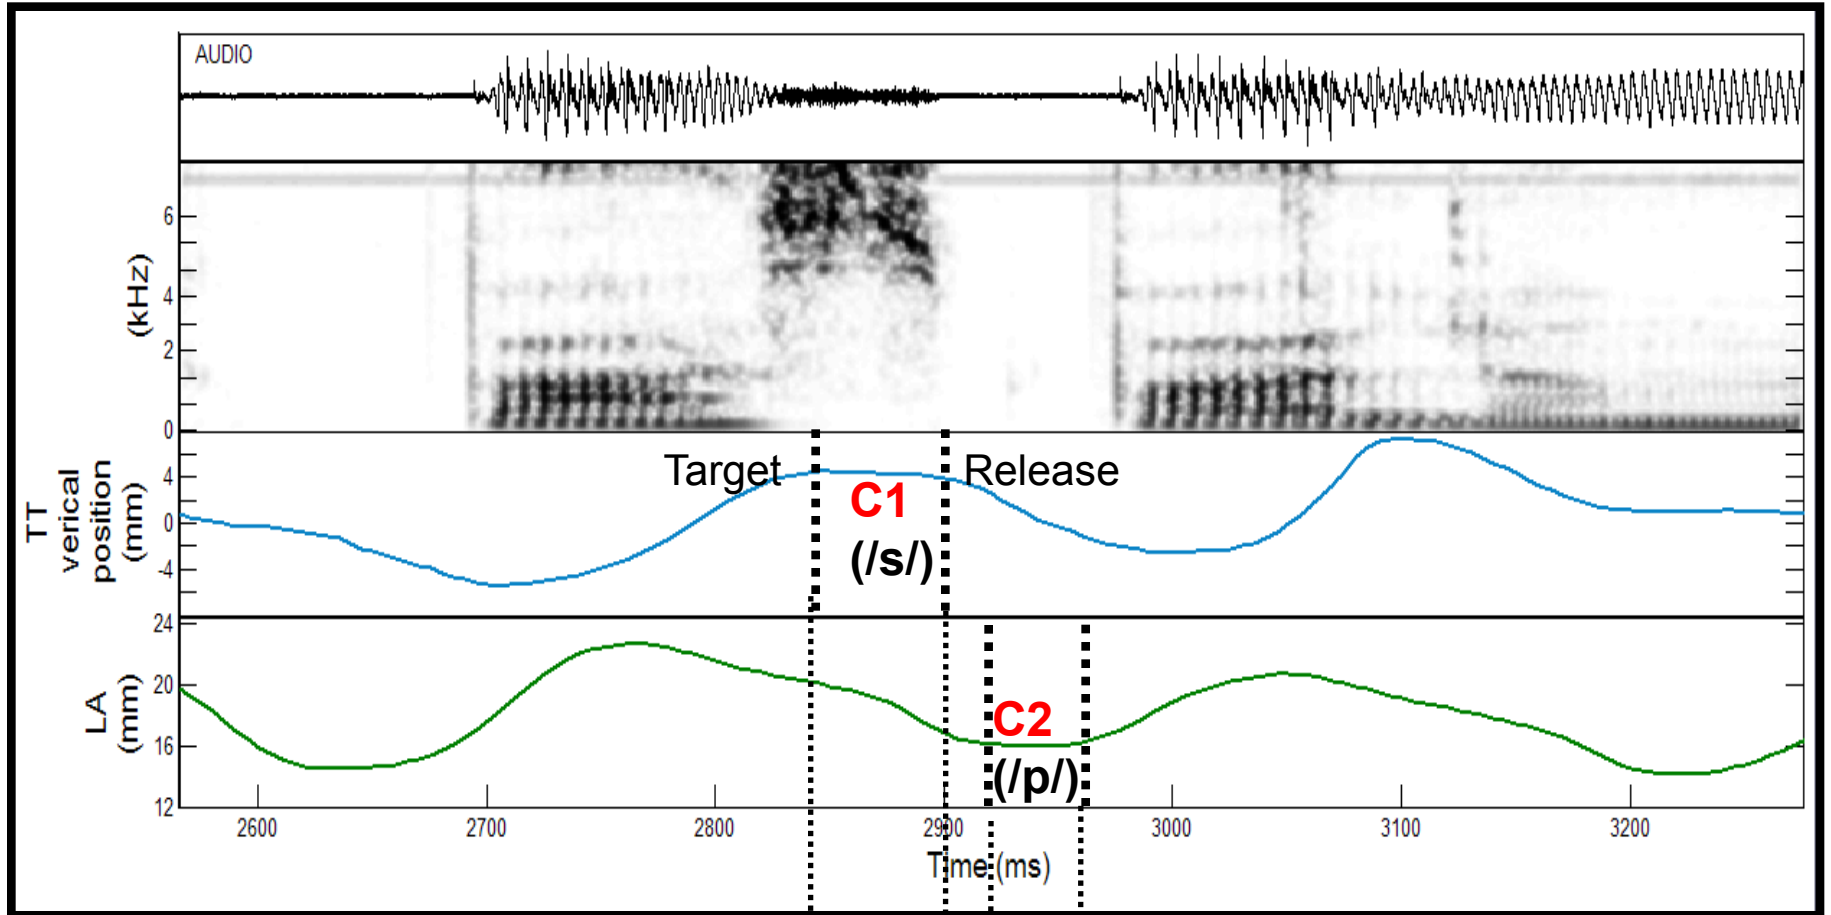

[p] – Lip Aperture

[s] – Tongue Tip vertical movement

[k] – Tongue Dorsum vertical movement

# Example: /spalə/

# Target-to-release lag analysis

Target-to-release lag = Target\_C2 – Release C1

Negative values indicate that the release of C1 is overlapped by C2

Positive values indicate C2 achieves its target after C1 release

Normalized lag = Target-to-release lag/Constriction duration

# Results

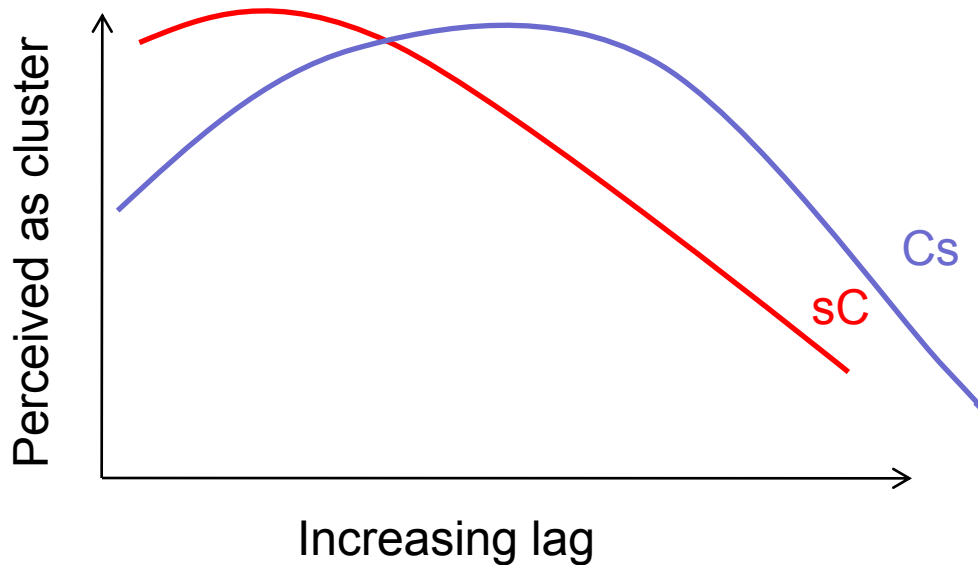

- sC-clusters have smaller lags than Cs (SP- vs. SK- n.s.)
  - Order effect significant for SP- vs. PS- (not for SK- vs. KS-, but KS- more variable)
    - Less lag for front-to-back clusters? No
    - More lag for labio-coronal/coronal-labial clusters? Yes for PS-, no for SP-
- More lag for Cs- than sC- onsets to ensure perception of stop released into sibilant?

# Perception Experiment

- Is more lag needed to perceive a Cs- than an sC-cluster?
- Is more lag permitted for Cs than sC before perception of cluster degrades?

# Materials

Stimuli (produced using the articulatory synthesizer TADA):

CC

**sC**: spad, skad

**Cs**: psad, ksad

CVC

**səC** (V ~40ms, ~20ms, ~10ms): səpad, səkad

**Cəs**: pəsad, kəsad

(cvc40, cvc20, cvc10)

- Cluster base stimulus – default TADA implementation for onset clusters
- Continuum: C2 started (and ended) +2/+4 frames later than preceding stimulus (1 frame ~ 10ms)
  - e.g. spad, spad2, spad4, spad8, spad12, spad16, spad20, spad24
  - (cc, cc2, cc4...)
  - cc12: C2-formation starts 1 frame after C1-release ends
  - cc24: C2-formation starts 13 frames after C1-release ends

# Method

13 listeners (Romanian native speakers)

DMDX presentation

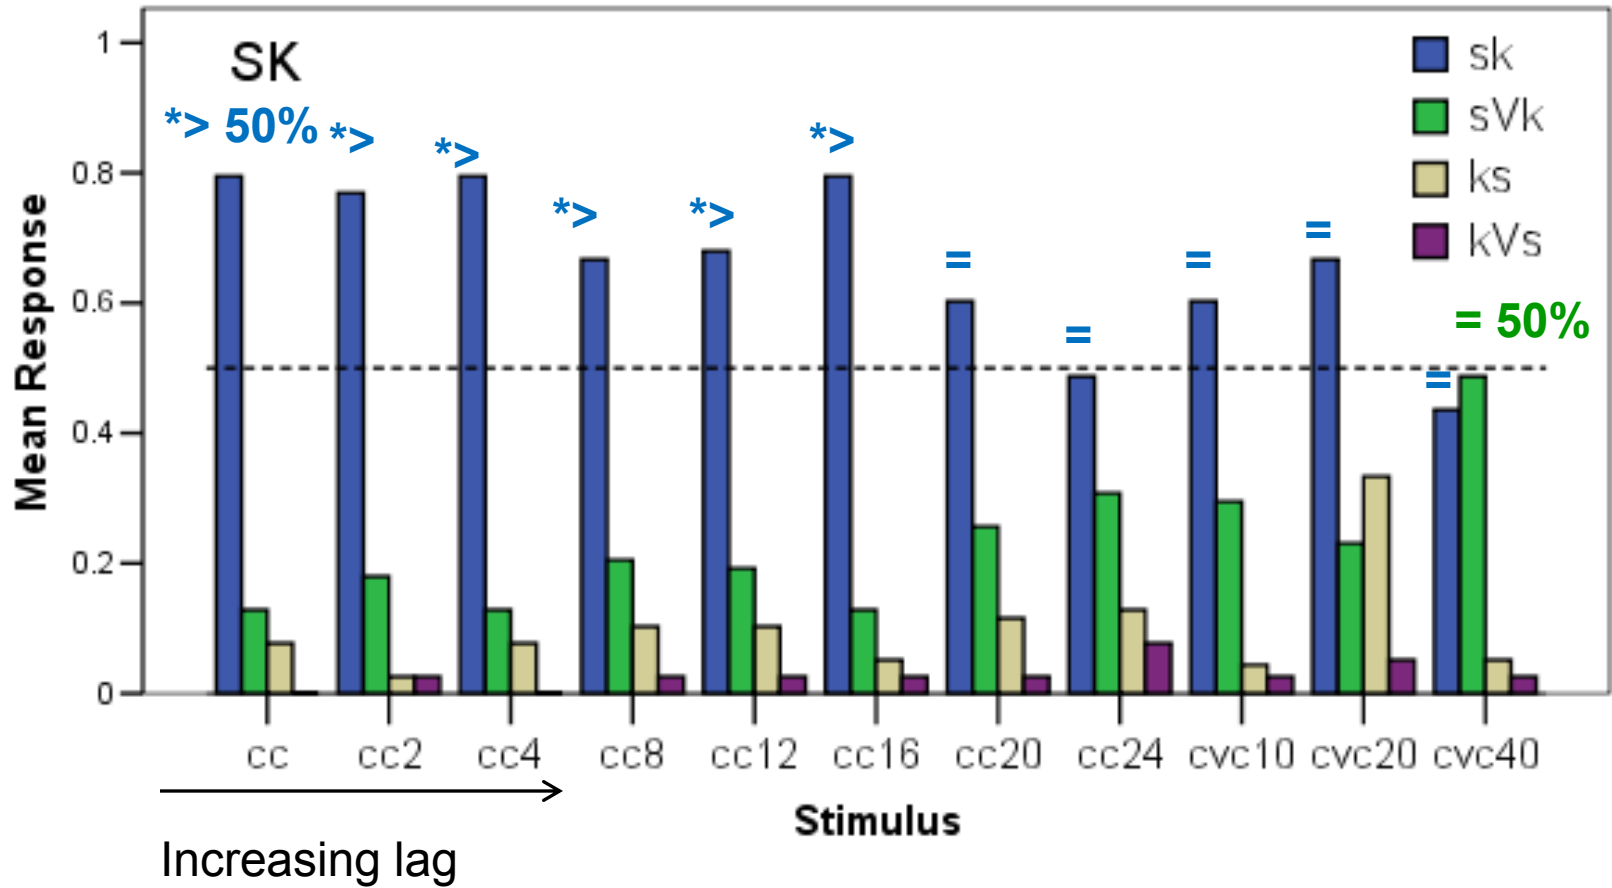

- Forced choice (separately for sp/ps, sk/ks, each stimulus heard 3 times): sp, ps, sVp, pVs/ sk, ks, sVk, kVs
- AXB (always presented last, each stimulus heard twice):
  - A/B: CC and CVC
  - X: CC, CC2, CC4... CC24, CVC

Choice presented orthographically

# Results forced choice

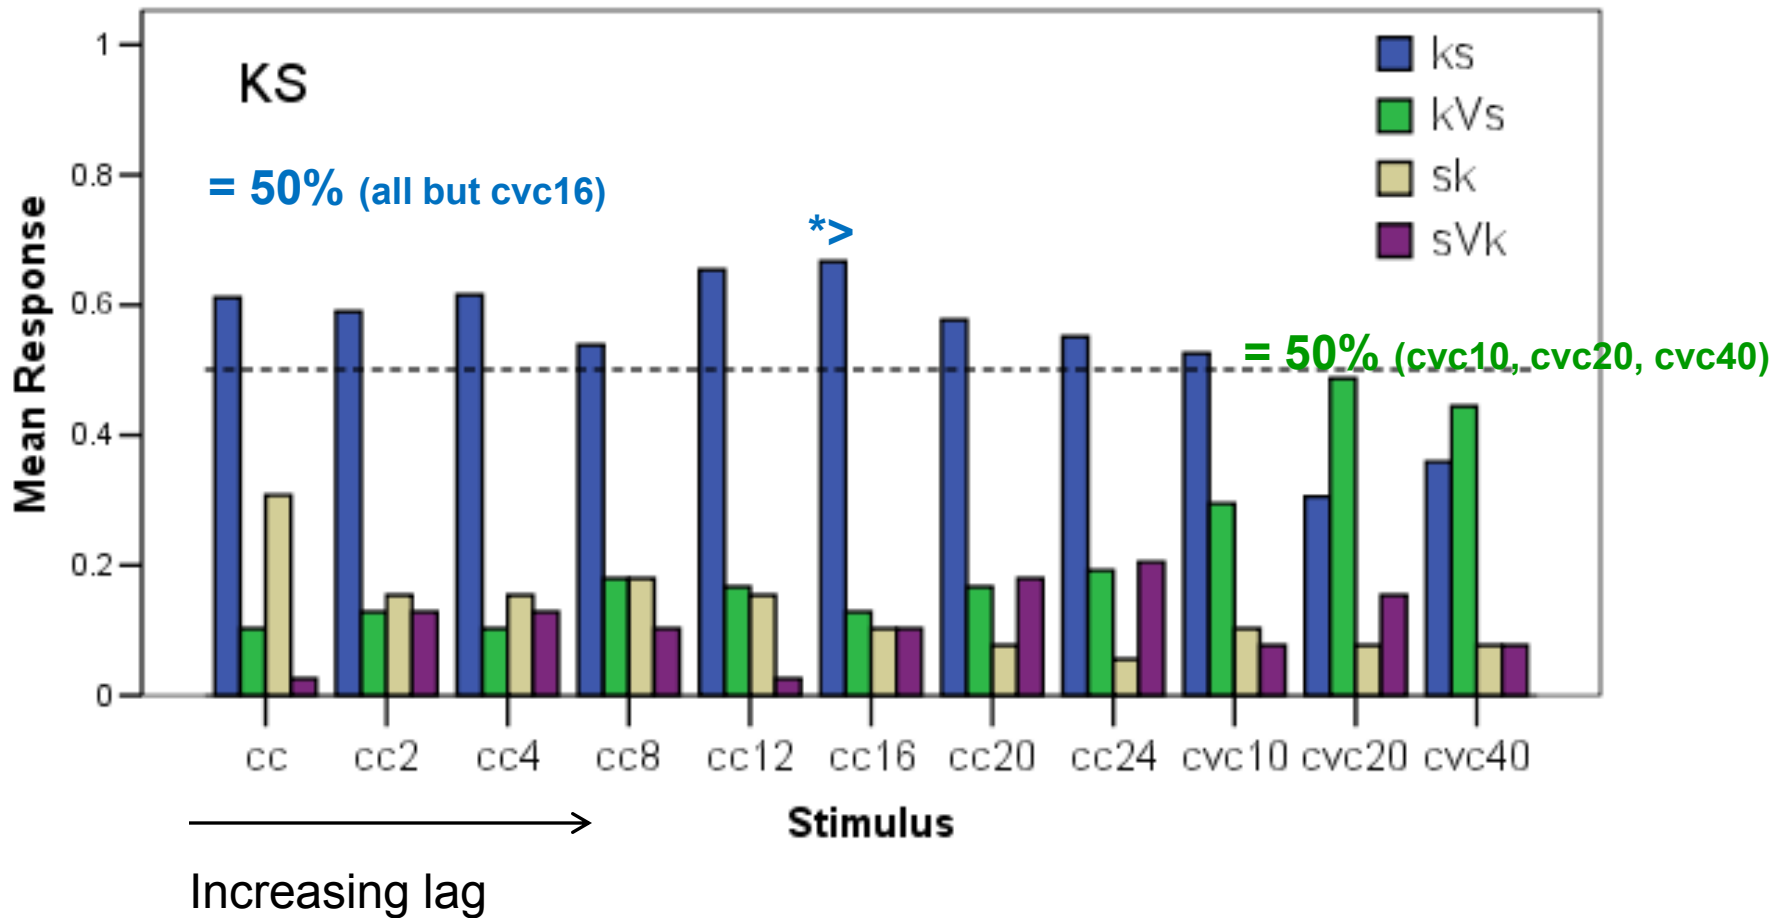

# Results forced choice

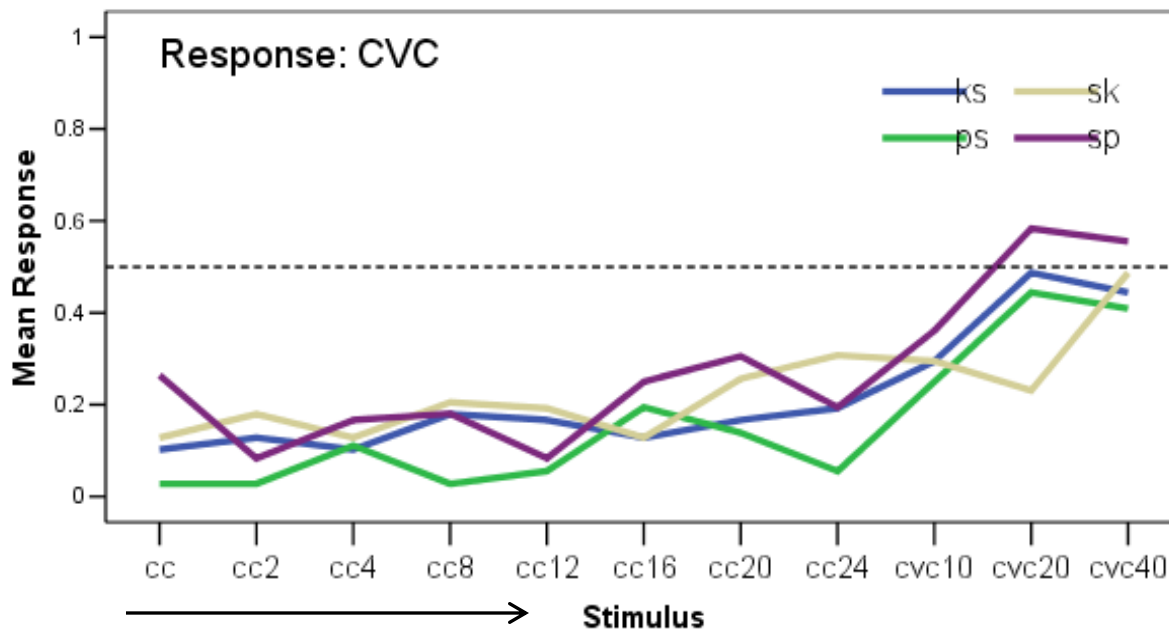

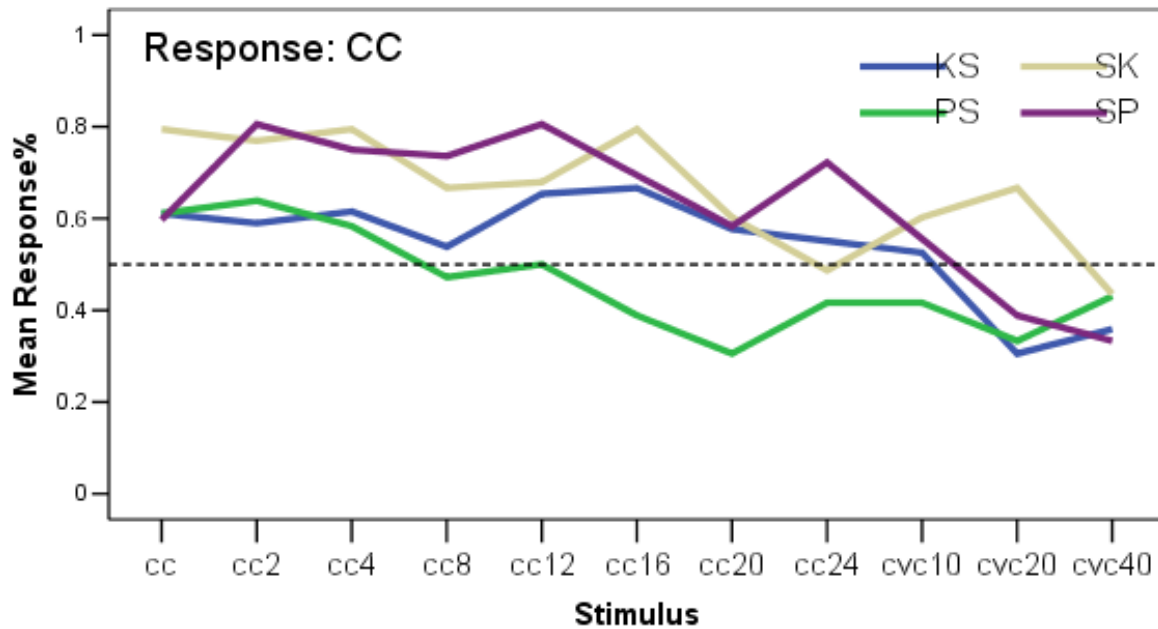

# Results forced choice

# Results forced choice

# Results forced choice

→  
Increasing lag

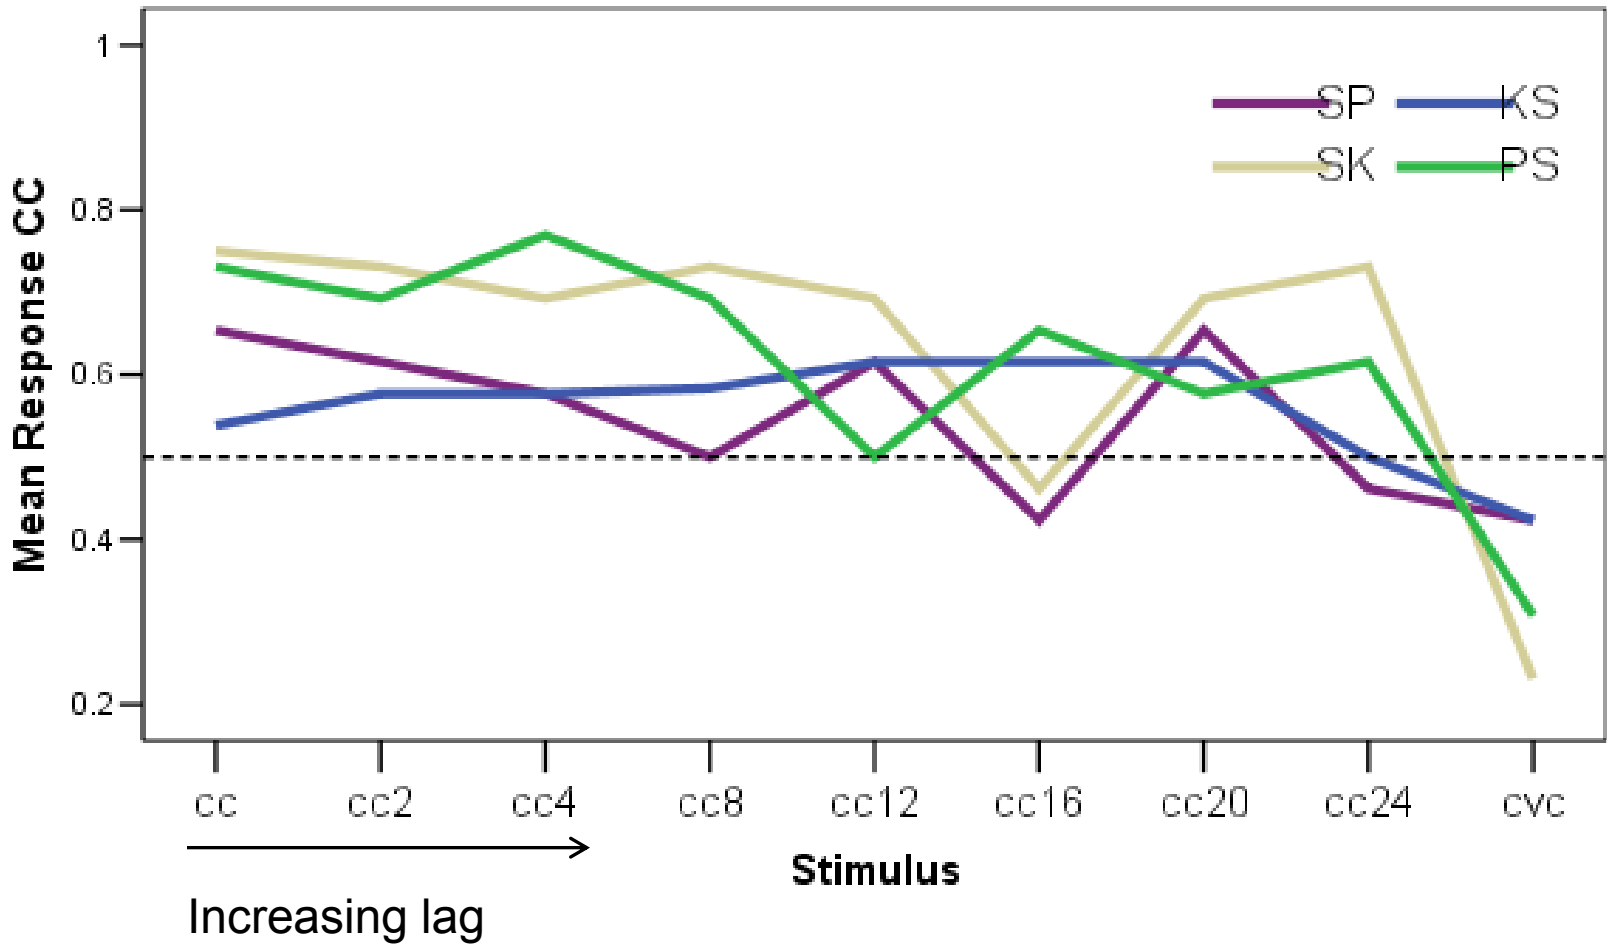

SK

KS

# Results AXB

SP, KS continua: not different from chance

SK: CC, CC2, CC4, CC8, CC20, CC24  $* > 50\%$ ; CVC  $* < 50\%$

PS: CC, CC2, CC4, CC8  $* > 50\%$ ; CVC  $* < 50\%$

# Discussion

- Is more lag needed to perceive a Cs than an sC cluster?
  - No – if anything, increased lag for /ps/ clusters leads to degradation of cluster percept
- Increased lag observed in production of Cs- may not be guided by perception requirements:
  - Larger lag in Cs- may be caused by the same mechanism that caused a shift away from the vowel (and vowel lengthening) → slowing down of production system
- Independent of lag manipulation, perception of Cs-cluster is overall less accurate than that of sC-clusters
